Herbaceous Peonies

HOW TO PLANT

HERE Peonies are to be planted in a bed, an excavation the full size of the bed should be made, two to three feet in depth. A layer, six inches in depth, of well-rotted manure (cow manure for preference) should then be laid in the bottom and well spaded in. If the soil taken out be of a loamy nature, such as will retain moisture, it should be mixed with a moderate amount of thoroughly rotted manure—not green manure. Should the soil excavated be of a stiff, clayey nature, mix with it sand, leafmold and rotted manure; the proportion should be two-thirds of the soil to one-third of the sand, leafmold and manure. The whole compost must then be thoroughly turned over and mixed, so that the entire mass is of even consistency. Fill up the excavation with this prepared soil, rounding it up at the center, so that it stands about eight inches above the level of the lawn.

In planting the roots, allow a space for each Peony equal to a circle three feet in diameter; this will allow for abundant growth. The crown of the Peony root should be set about three inches below the surface of the soil. Firm the earth well around the roots. After the bed is planted, cover the whole with a mulching, three or four inches deep, of course, strawy manure or leaves.

WHEN TO PLANT

The best time to plant Peonies is from about the middle of August until the end of September. This early planting enables the roots to become thoroughly established before frost sets in. They can be planted as late as November, but such late planted roots just remain dormant in the ground until Spring comes.

TREATMENT

There is no plant that will thrive more and require less treatment than the Peony. Each Fall, after the ground has been frozen, cut off the tops of the Peonies about three inches from the ground. The tops may be thrown back upon the bed to serve as a mulching, on top of which should be spread a liberal dressing of coarse manure. In the Spring this mulching should be shaken up and the coarse parts removed from the bed. The remaining stuff should be spaded carefully into the bed, and the surface around the crowns of the plants stirred up, care being taken not to break the dormant crown buds. During extreme drought in April or May drench the beds thoroughly with water once or twice a week. Where largest flowers are wanted, disbudding can be done by removing the smaller buds and leaving only the center bud on each stem.
